Variations in the intensities received at one ear are
measured while a steady tone of the same frequency is
measured at the other ear. Examination of the response
curves and their slopes in the middle portion, as well as
of the differential thresholds, shows that there is always
an attenuation in differential sensitivity. This phenom-
enon will be the more pronounced, the higher the inten-
sity of tone on the other ear. It can be assumed that this
effect is of cortical origin and is, perhaps, a question of
contrast. (Author)

According to the statistical studies carried out in this
work, the differential thresholds obtained by measuring
the intensity variations on one ear while simultaneously
applying a steady tone of the same frequency to the
other ear, are the higher, as the tone is binaurally in
phase, and are the lower if the tone is out of phase,
provided the frequency is lower than 1000 cycles/sec -
